

# **Principles of Programming Languages**

CS 245 — Spring 2019  
[kmicinski.com/cs245](http://kmicinski.com/cs245)

**Kristopher Micinski**

Jocelyn Dunkley    Myriam (Mimi) Benkoussa

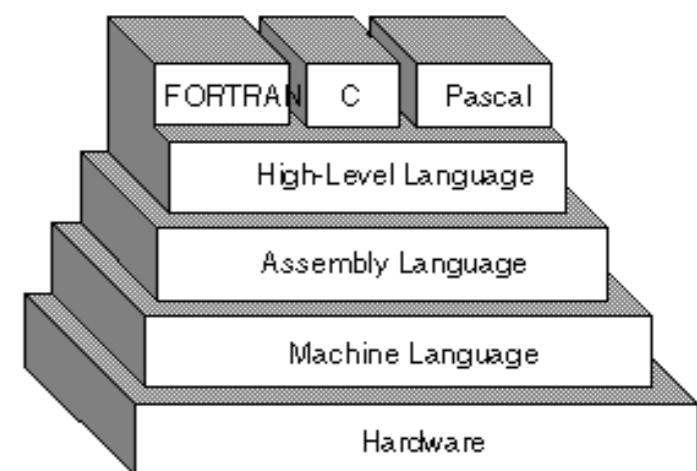

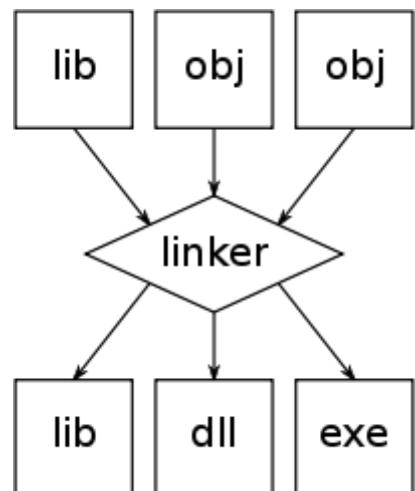

This class is about the **principles** of programming languages:

what kinds of languages are there?  
how do they work “under the hood”?  
how are they implemented?

We’re also going to learn 4-8, or more (depending on how we count), different programming languages!

**First, a bit of history...**

Humans create tools to help them solve problems

Programming Languages allow us to *precisely* express  
solutions to certain classes of problems

**How do we (partially) formally specify what we want?**

**How do we (partially) formally specify what we want?**

**How do we write a program that does what we want?**

How do we (partially) formally specify what we want?

How do we write a program that does what we want?

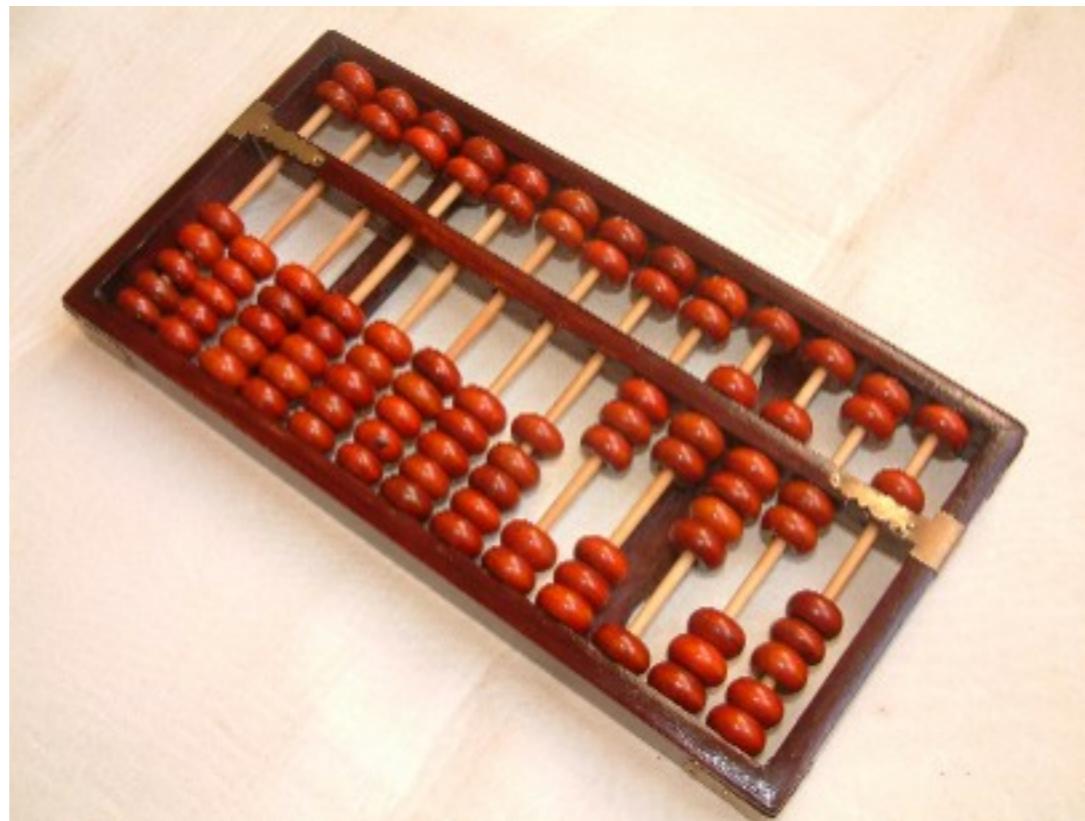

How do we run that program?

How do we (partially) formally specify what we want?

How do we write a program that does what we want?

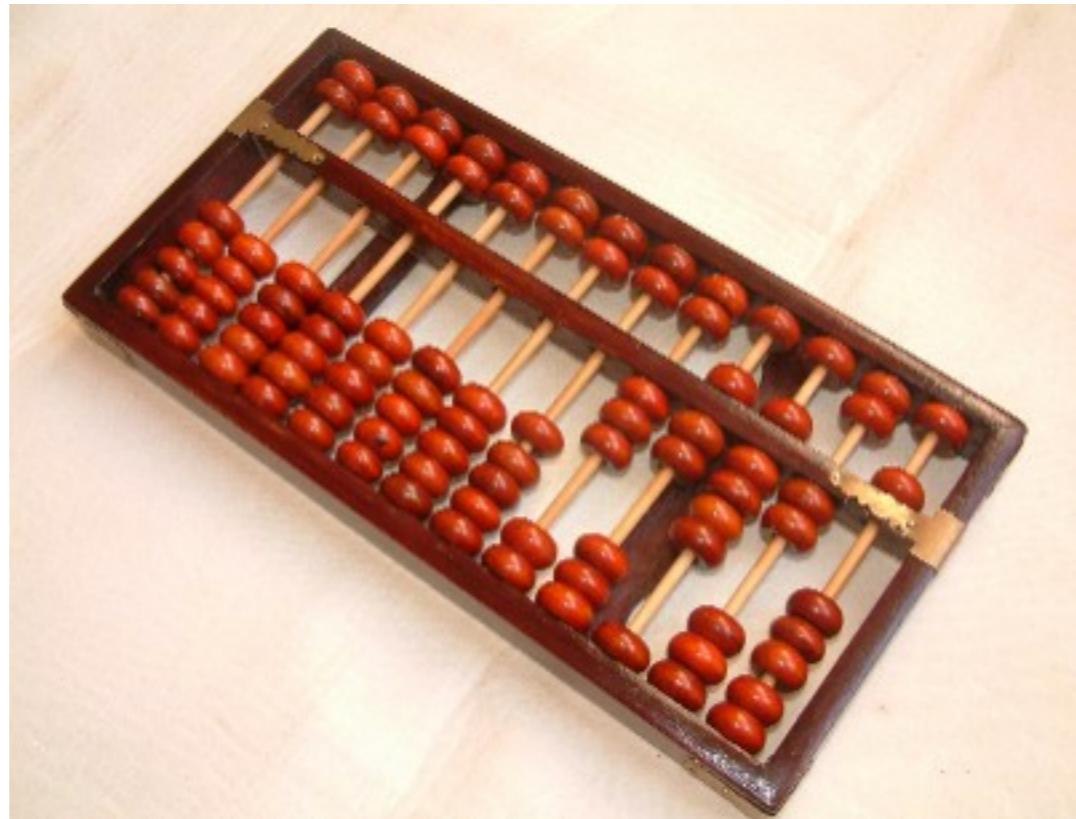

How do we run that program?

How can we be convinced that program is correct?

**~500 BC**

Allows us to solve arithmetic problems (if you know how to use it)

**~500 BC**

Not really a program, but machine that allows us to perform computation

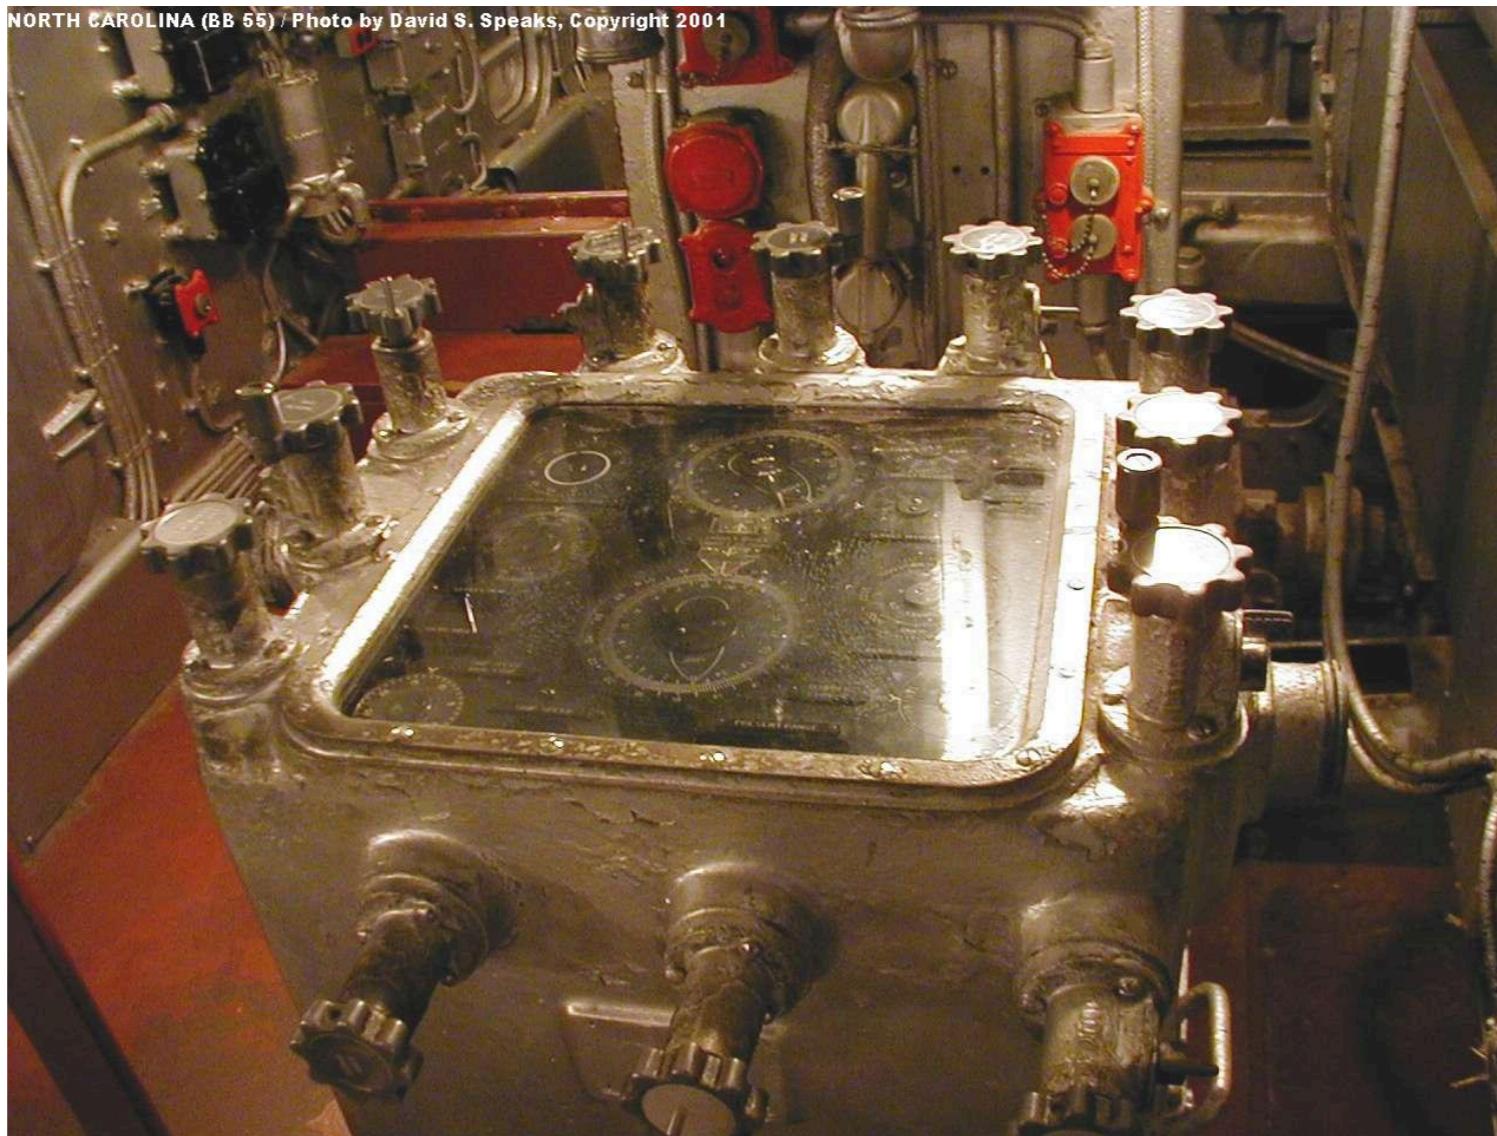

# Jacquard Loom (1804)

Reads punched cards to build, e.g., tapestries

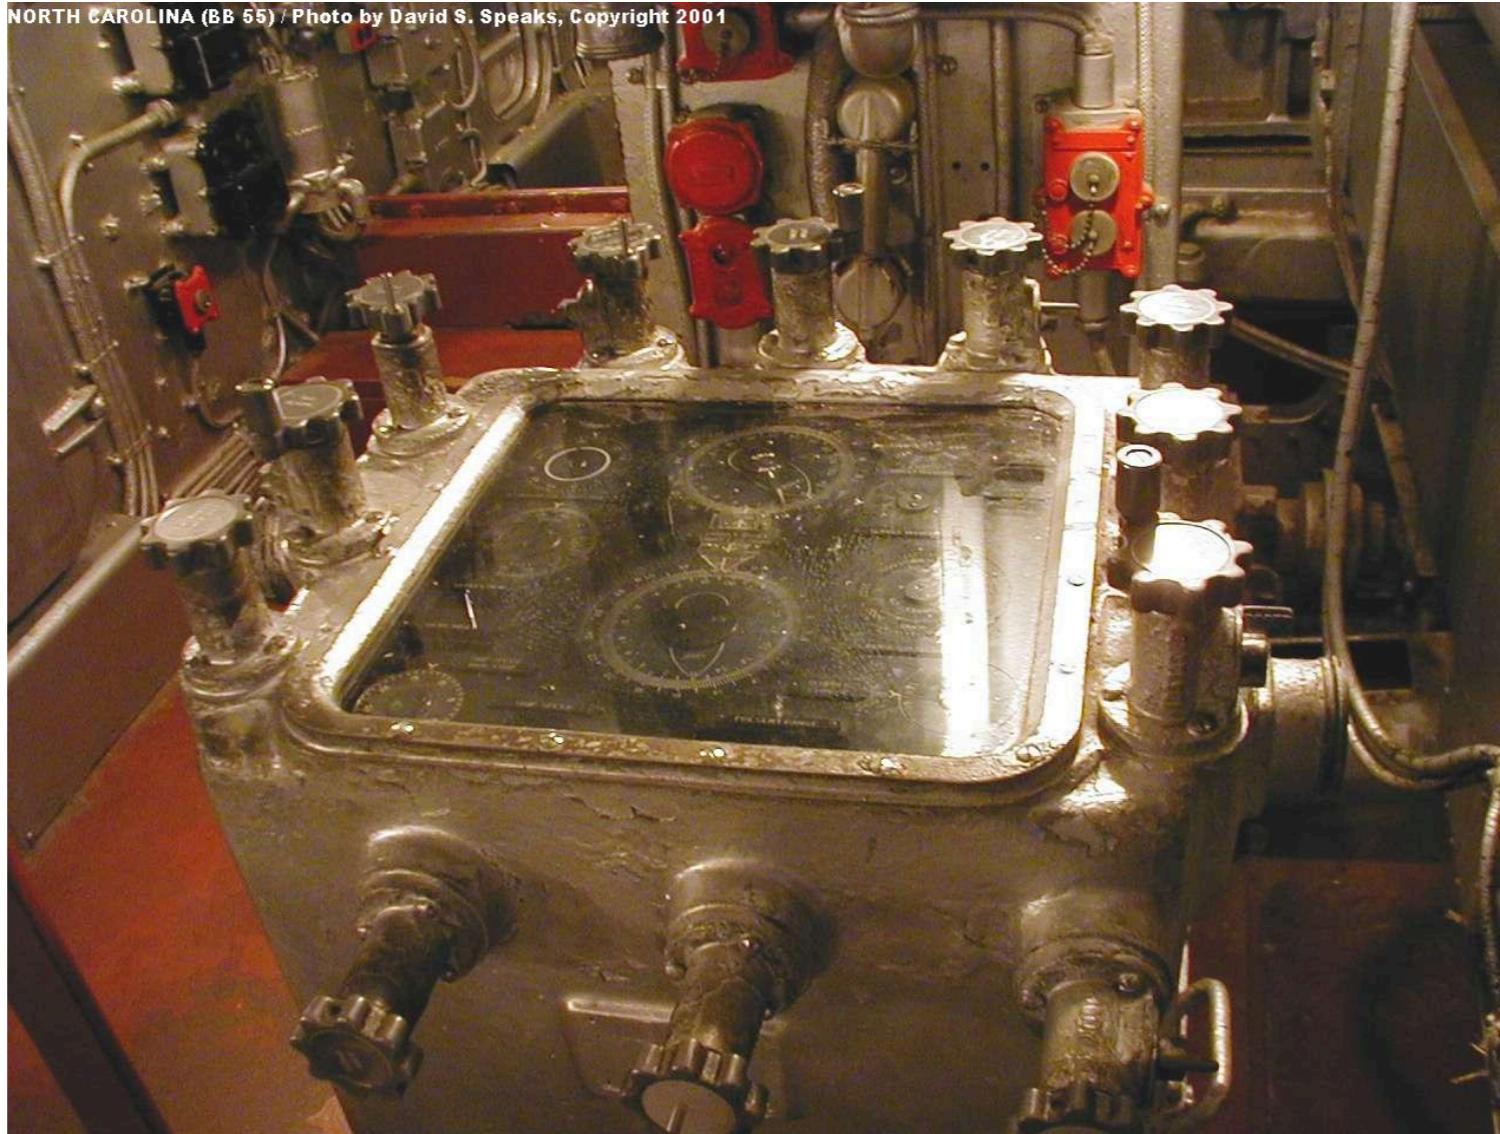

You write a **program** to build the material

<https://www.youtube.com/watch?v=OIJns3fPltE>

Analog targeting computer (USS North Carolina)  
Helps aim guns given target distance / speed  
Works using gears..

# Not general purpose!!!

Analog targeting computer (USS North Carolina)

Helps aim guns given target distance / speed

Works using gears..

## Ada Lovelace

Translated memoir describing general-purpose computer (1842)  
Wrote notes of how to use this to compute Bernoulli numbers

Alonzo Church

Created lambda calculus (1936)

Alonzo Church

Created lambda calculus (1936)

Lambda calculus:  
mathematically specified language

Notably: a **general purpose**  
language

But **ridiculously simple**

$$\begin{array}{l} e ::= \\ \quad x \\ \quad | \lambda x. e \\ \quad | e e \end{array}$$

At this time, there were no “computer scientists”  
Most people studying this were mathematicians, engineers, etc...

Also, nobody had actually **built** a general-purpose computer

So we were free to think about what languages would look like  
without thinking about hardware

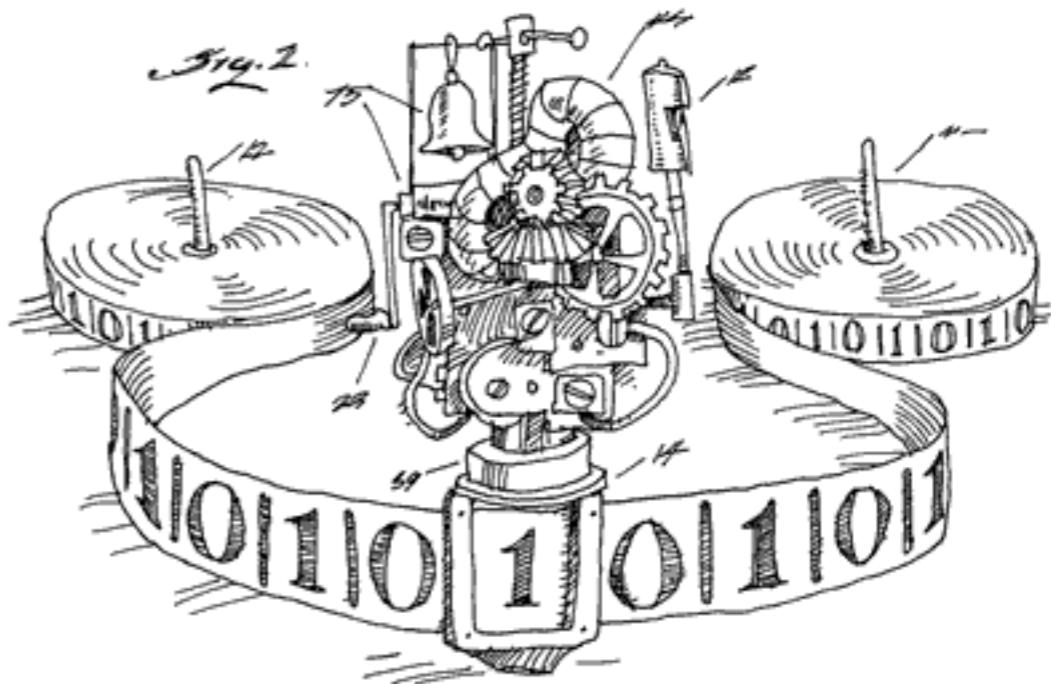

**Alan Turing (Church's Student)**

Invented Turing machines (1936)

# Alan Turing

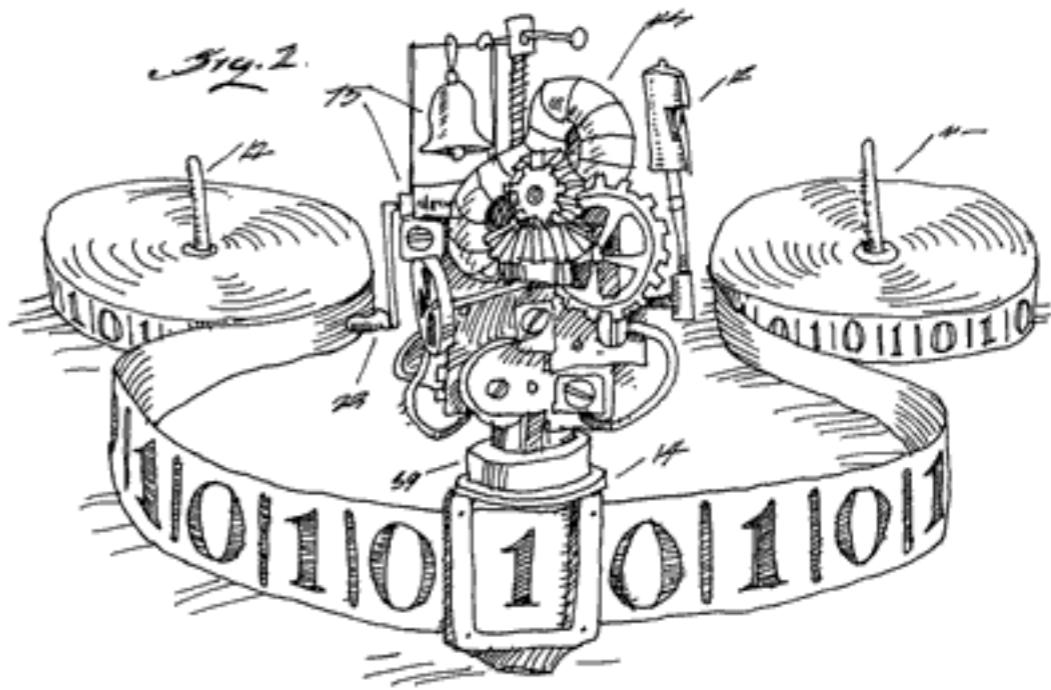

Model of computation that includes:

- Read / Write Tape (memory)
- Head (current position on tape)
- Current state
- Instructions

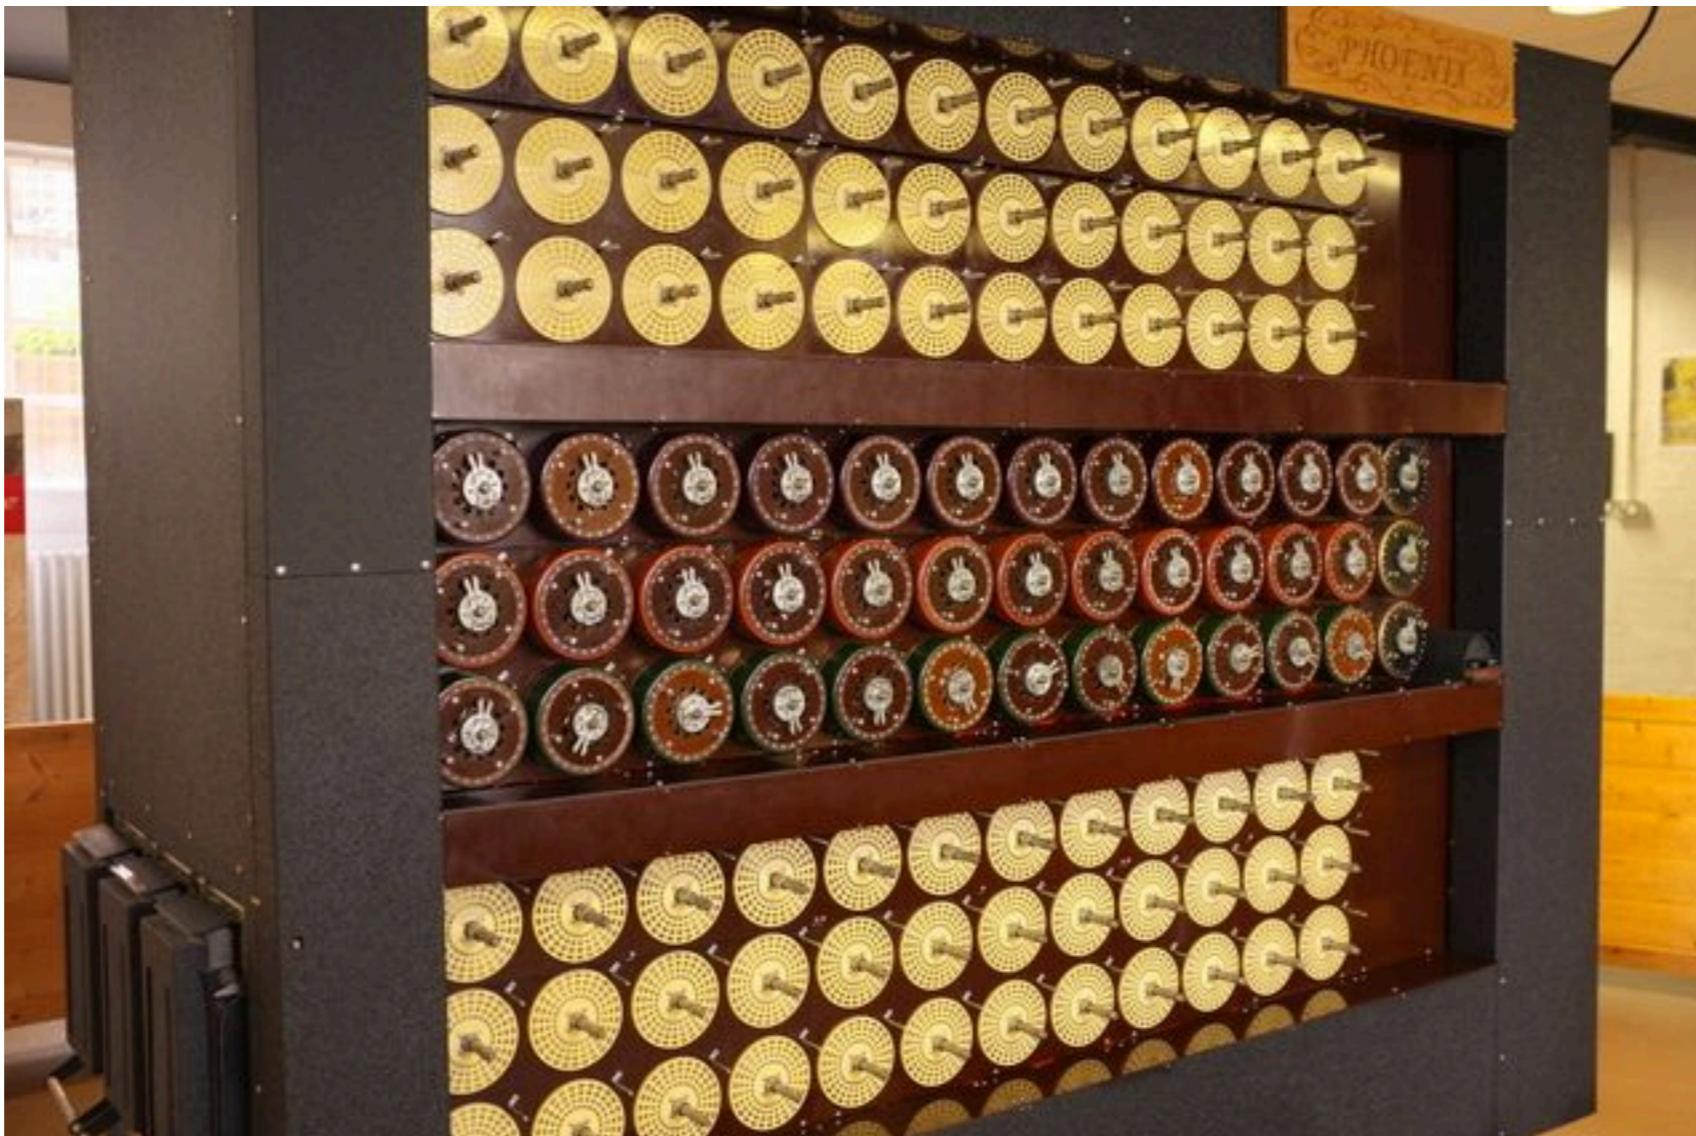

# Alan Turing

Model of computation that includes:

- Read / Write Tape (memory)
- Head (current position on tape)
- Current state
- Instructions

Church-Turing Thesis:  
Any **computable** function can be  
computed by some Turing machine

## Turing's Bombe

Cracks enigma by semi-brute-force exploiting a flaw in  
German code scheme

## Alan Turing

Even after his work cracking enigma, Turing was  
prosecuted for his homosexuality

He committed suicide at the age of 41

Several general-purpose languages came about, mainly targeted at mechanical computers in the early 50s

These languages mostly resembled Turing machines and grew into the assembly languages we see today!

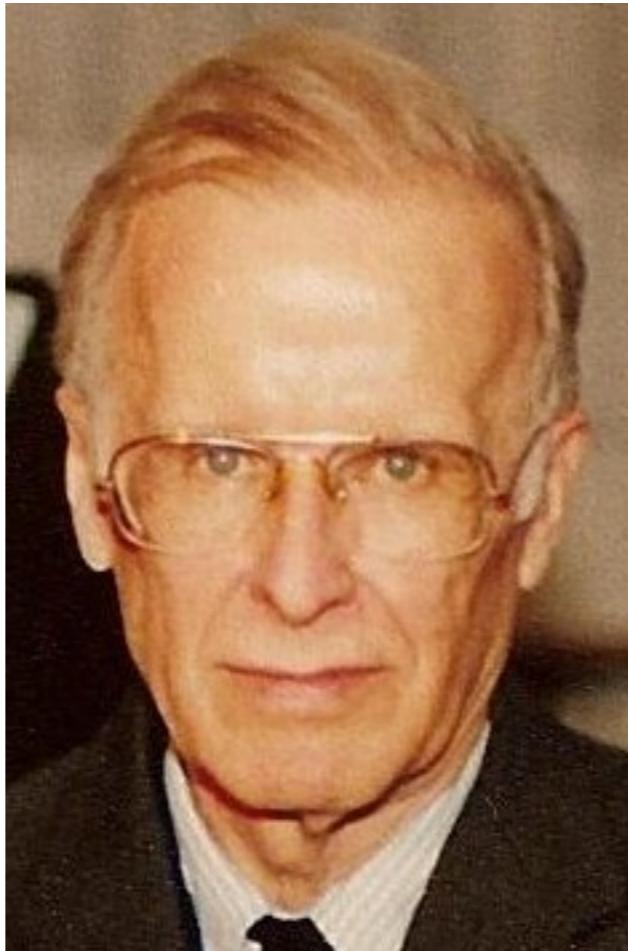

# Corrado Böhm

Wrote first meta-circular compiler (1951)

In only 114 lines of code

# John Backus

1954 — FORTRAN invented at IBM

First general purpose language w/  
compiler that had widespread use

Also invented BNF

# Grace Hopper

1955—Writes FLOW-MATIC (inspires COBOL)

# John McCarthy

1958—Invents LISP (inspiration for Scheme/Racket)

Gets variable scoping **wrong** because he failed  
to read **all** of Church's 1936 paper...

“To use functions as arguments, one needs a notation for functions, and it seemed natural to use the  $\lambda$ -notation of Church (1941). I didn’t understand the rest of his book, so I wasn’t tempted to try to implement his more general mechanism for defining functions.”

“I must confess that I regarded this difficulty as just a bug and expressed confidence that Steve Russell would soon fix it. He did fix it but by inventing the so-called FUNARG device that took the lexical environment along with the functional argument. Similar difficulties later showed up in Algol 60, and Russell’s turned out to be one of the more comprehensive solutions to the problem.”

—John McCarthy, History of Lisp, 1979

<http://jmc.stanford.edu/articles/lisp/lisp.pdf>

Remember this when we talk about closures :-)

# Margret Hamilton

1960s: leads team that writes assembly code for  
Apollo rockets / lunar module / command module

# Margret Hamilton

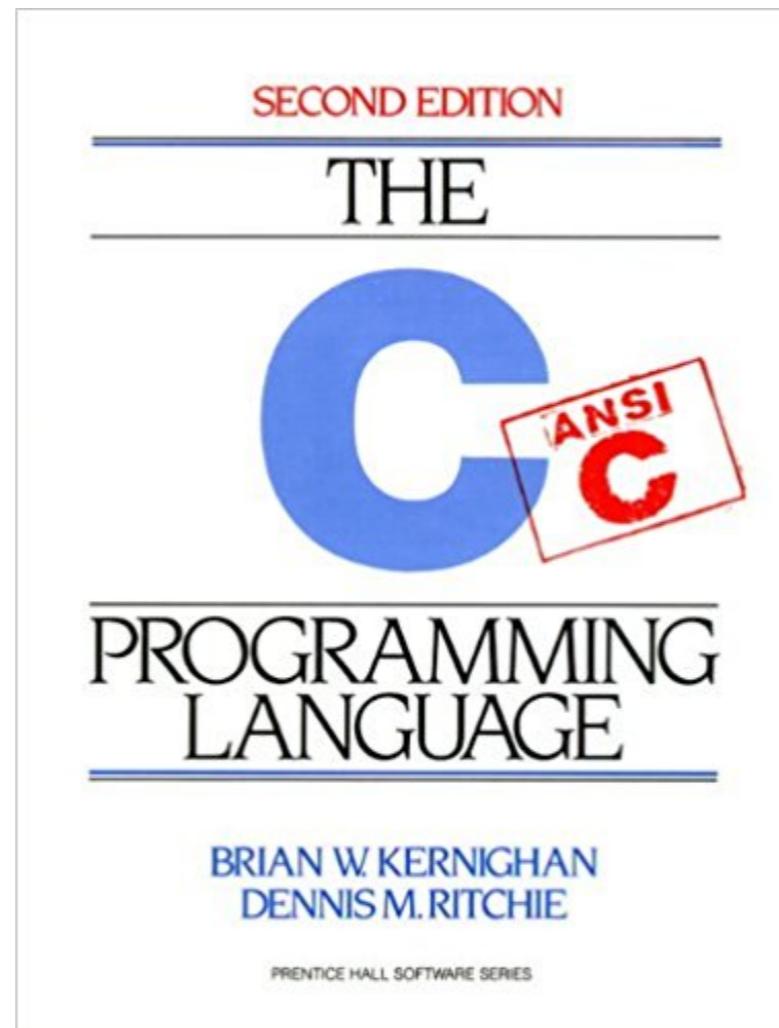

Think of how much testing this required!  
Amazing what people can do even w/ weak languages!

Mid 60s: Ken Thompson and Dennis Ritchie get fed up  
hacking on the crummy code in MULTICS

Start writing UNIX for fun to get away from their bad  
code—First versions written in **assembly** in 1969

Writing in assembly is error-prone, so they created the C programming language—a derivative of BCPL (language around Bell labs at the time)

Early 70s: rewrite UNIX in C, create most famous operating system of all time  
(My Mac's kernel is based on UNIX!)

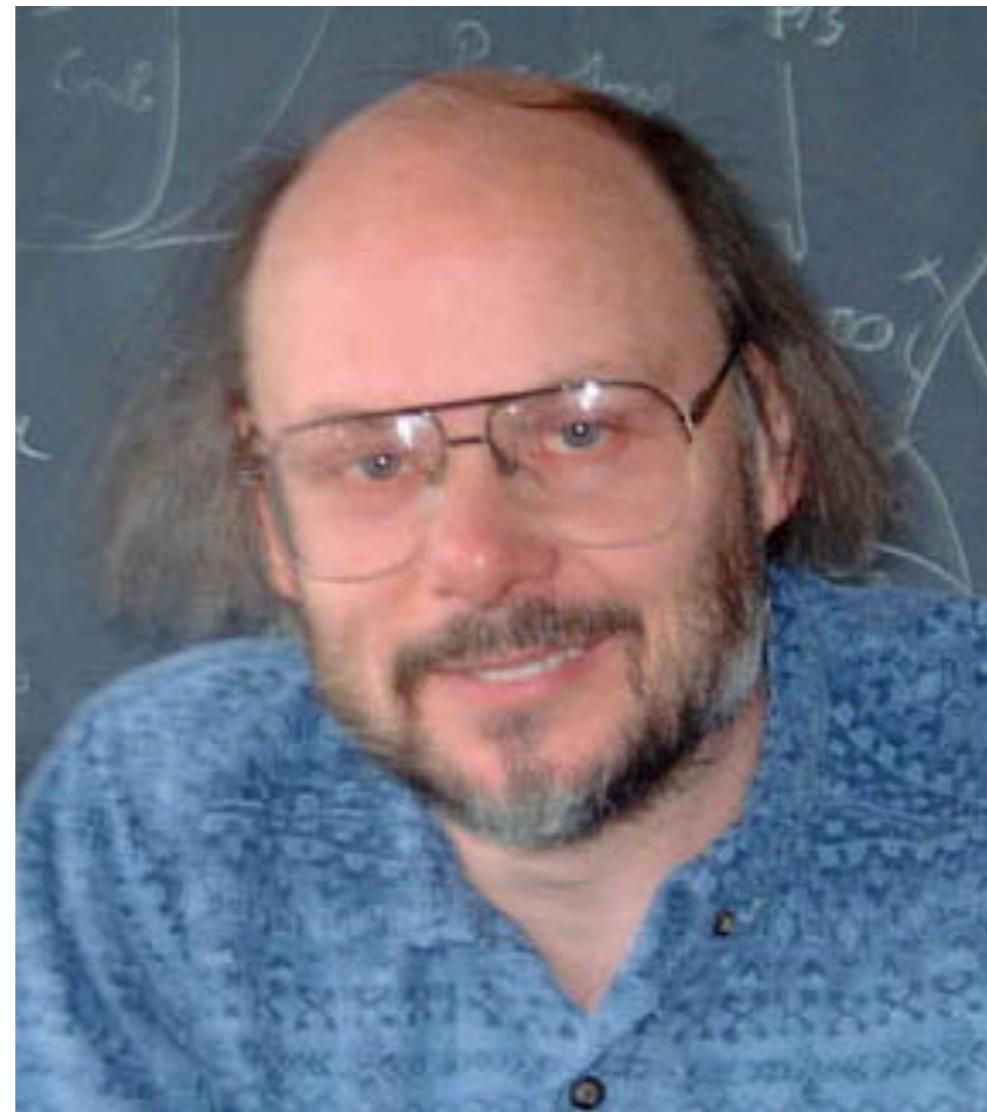

# Barbara Liskov

Early 70s: CLU—classes, abstract types, iterators

Liskov Substitution Principle: subtyping!

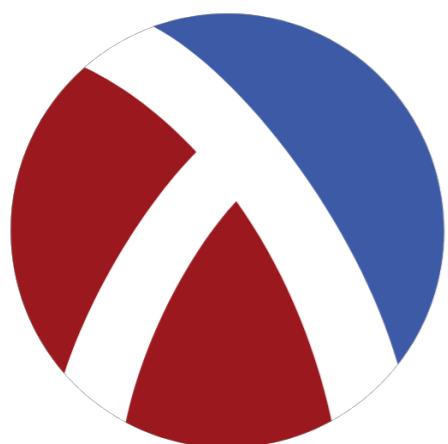

# Bjarne Stroustrup

1979—Extended C to add classes, creates  
C++ (or C with classes)

And many others...!

**Now, back to the lowest level...**

# Binary: The native language of the processor

- Modern processors are *very fast*
- (*m/b*)illions of *instructions* per sec

Processors execute a small number  
of *very basic* instructions

MOV r1, r2    ADD r1, r2,r3

IFZERO r1, +20

These instructions written in a binary encoding  
**(Why?)**

# Binary: The native language of the processor

- Modern processors are *very fast*
- (*m/b*)illions of *instructions* per sec

Processors execute a small number  
of *very basic* instructions

MOV r1, r2    ADD r1, r2,r3

IFZERO r1, +20

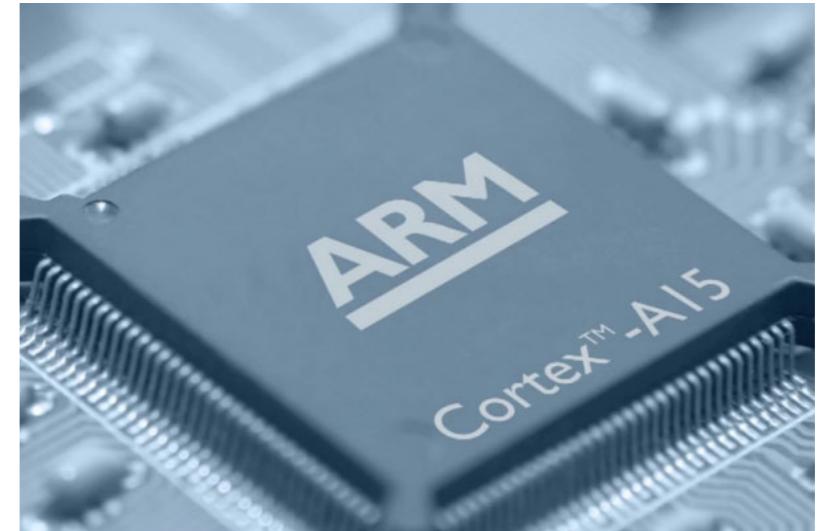

These instructions written in a binary encoding  
(Why?)

Compact representation

Quick to decode and execute

# Thousands of different processors

Each speaks a different language

Called its *architecture*

Different versions of architecture add features, etc..

eclipse-workspace - sumnums/src/sumnums.cpp - Eclipse

```
1 #include <iostream>
2 #include <string>
3 using namespace std;
4
5 int sum(const unsigned int number) {
6     int i = number;
7     int accumulator = number;
8     while (i > 0) {
9         accumulator += i;
10        i--;
11    }
12    return accumulator;
13 }
14
15 // This program accepts 1 argument
16 int main(int argc, char *argv[]) {
17     int number;
18
19     if (argc < 2) {
20         cerr << "This program needs at least one argument.\n";
21         exit(1);
22     }
23
24     try {
25         number = stoi(argv[1]);
26     } catch(const invalid_argument& ia) {
27         cerr << "Invalid argument: " << ia.what() << '\n';
28         exit(1);
29     }
30
31     if (number < 0) {
32         cerr << "This program expects a non-negative argument.\n";
33         exit(1);
34     }
35
36     cout << "I am going to sum the numbers from 0 to " << argv[0] << "\n";
37     cout << "Sum: " << sum(number) << "\n";
38
39     return 0;
40 }
```

So I need to turn this into something my i7 speaks...

To do that, I use a *compiler*

“Compile a file named sumnums.cpp, and output an executable file named sumnums”

```
clang++ sumnums.cpp -o sumnums
```

“Compile a file named `sumnums.cpp`, and output an executable file named `sumnums`”

```
clang++ sumnums.cpp -o sumnums
```

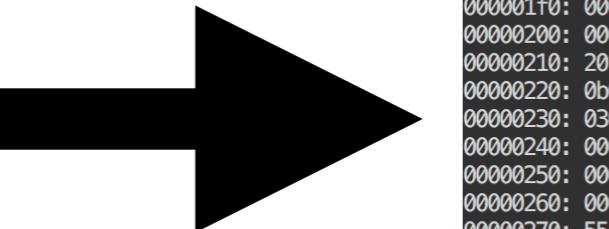

(*Ton* of options here, especially for large projects with complex configs / multifiles)

eclipse-workspace - sumnums/src/sumnums.cpp - Eclipse

```

1 #include <iostream>
2 #include <string>
3 using namespace std;
4
5 int sum(const unsigned int number) {
6     int i = number;
7     int accumulator = number;
8     while (i > 0) {
9         accumulator += i;
10        i--;
11    }
12    return accumulator;
13 }
14
15 // This program accepts 1 argument
16 int main(int argc, char *argv[]) {
17     int number;
18
19     if (argc < 2) {
20         cerr << "This program needs at least one argument.\n";
21         exit(1);
22     }
23
24     try {
25         number = stoi(argv[1]);
26     } catch(const invalid_argument& ia) {
27         cerr << "Invalid argument: " << ia.what() << '\n';
28         exit(1);
29     }
30
31     if (number < 0) {
32         cerr << "This program expects a non-negative argument.\n";
33         exit(1);
34     }
35
36     cout << "I am going to sum the numbers from 0 to " << argv[0] << "\n";
37     cout << "Sum: " << sum(number) << "\n";
38
39     return 0;
40 }
41

```

# Compiler

```

```

So, the compiler turns C++ into a giant list of these instructions...

So, the compiler turns C++ into a giant list of these instructions...

These are written in *assembly*  
(Human-readable binary)

**Let's see what  
assembly the  
compiler generates...**

```
clang++ -S sumnums.cpp
```

(Note I really used:

```
clang++ -S sumnums -fno-asynchronous-unwind-tables
```

This is because otherwise extra debugging overhead is inserted.)

```

Don't worry that this code is hard to understand for now

Divided up by function

Implementation of main

(It also confuses me..)

I can manually transform the assembly  
to the binary...

as sumnums.s

```
Kyles-MacBook-Pro-2:src micinski$  
Kyles-MacBook-Pro-2:src micinski$ ./sumnums.o  
-bash: ./sumnums.o: cannot execute binary file  
Kyles-MacBook-Pro-2:src micinski$
```

Crud...

For example: code to print to the screen

**Insight: my program  
needs a lot of other  
stuff to run...**

This is kept in a *library*

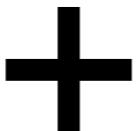

(But keep in mind, that's also **just code**. Nothing particularly magical)

# lstdc++

# Your code

# Syllabus

<http://kmicinski.com/cs245/syllabus/>

**A draft is freely available at: [isocpp.org/tour](http://isocpp.org/tour)**

# Grade breakdown

**50%** : ~8 coding projects

**10%** : weekly labs

**35%** : Two midterms (~6 weeks in and ~12 weeks in)

**5%** : Participation (graded in various ways)

# Autograder

# Academic honesty

**All submissions are graded using Clang 5, Racket 7, Python 3.7  
on an Ubuntu 18.04 LTR server.**

**If you have any trouble configuring this (or a compatible environment)  
on your home machine, I highly recommend you develop with:**

**VirtualBox**

# **What programming paradigms have you heard of?**

See if you know (or know of) any that  
your neighbors don't—or vice versa.

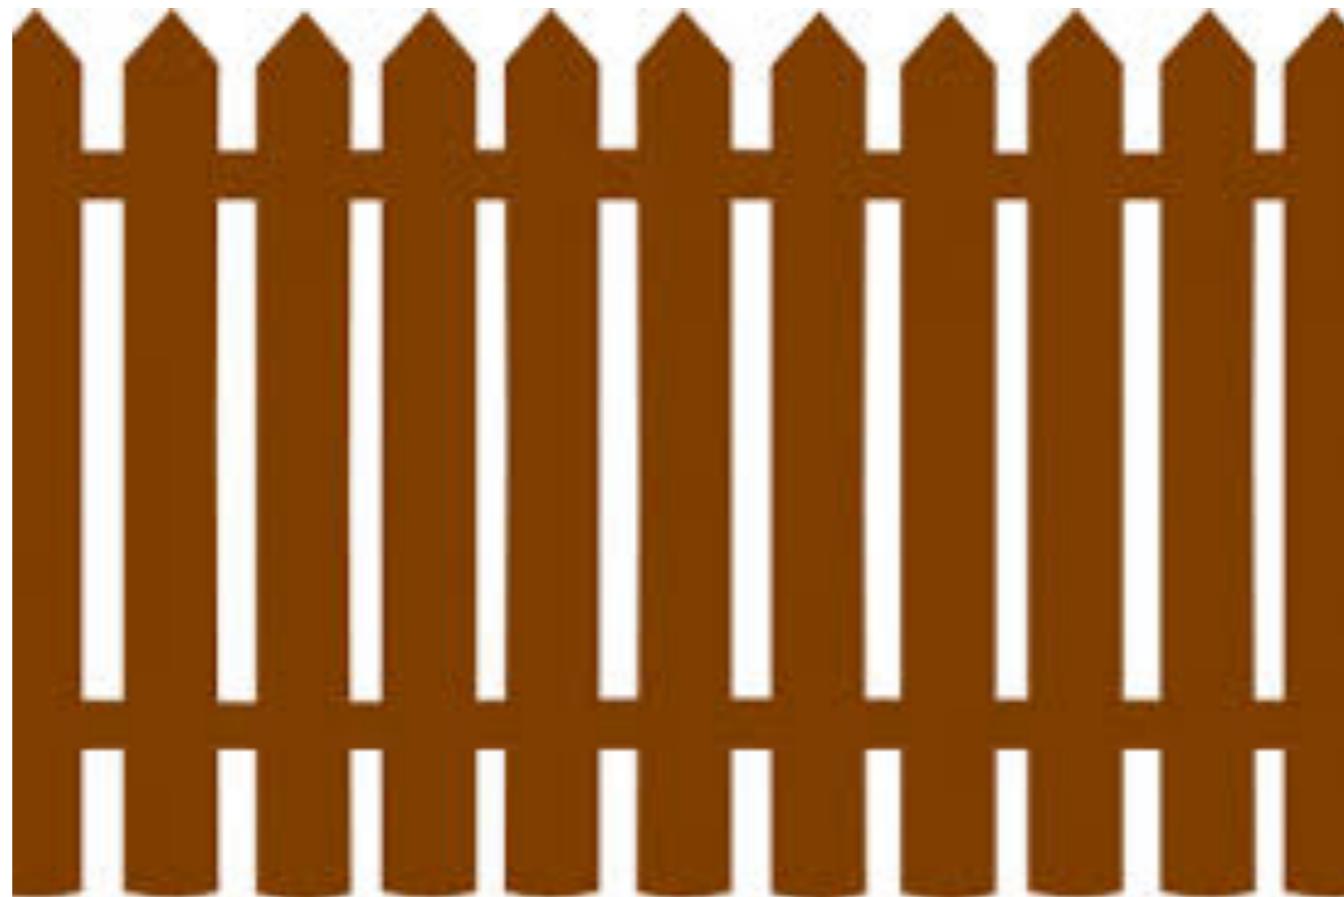

# Programming languages: paradigms

- **Imperative languages** emphasize issuing commands that tell the machine what *to do next* at each step of evaluation.
- **Structured languages** emphasize structured control-flow (i.e., not goto) that can be properly nested, especially sequencing, conditionals, and looping constructs (while, for, do).
- **Procedural programming** is imperative programming with subroutines —emphasizes abstracting behaviors over data.
- **Object-oriented programming** emphasizes encapsulation of behaviors (methods) and data (fields) within classes, abstract modular schema for program values, that are instantiated as objects at run-time. Inheritance hierarchies used to promote code-reuse.
- **Reactive programming** emphasizes responding to events.

# Programming languages: paradigms

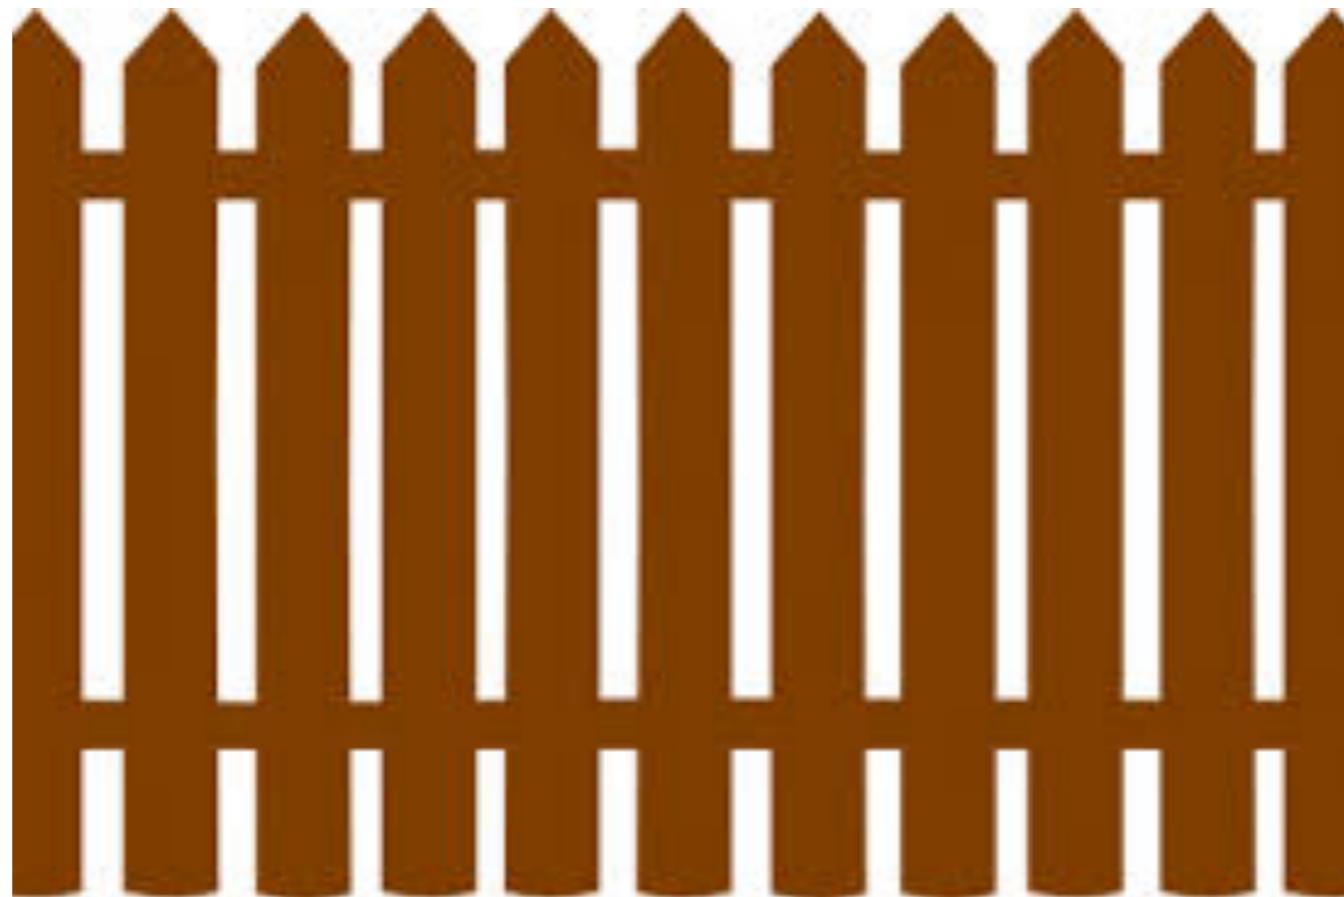

- **Dynamic languages** emphasize permitting arbitrary manipulation of program values, control, and the environment at runtime. Primarily these use duck typing / structural typing. A related paradigm is that of **reflective programming**—dynamically modifying types at runtime.
- **Static languages** emphasize bounding program behavior ahead-of-time. Primarily these use nominal typing and are type-checked.
- **Array languages** emphasize concisely manipulating arrays, matrices.
- **Functional programming** emphasizes immutability, like math. Programs are constructed from pipelines of composed functions that transform inputs to outputs without affecting their environment.
- **Logic programming** emphasizes declarations, propositions, logical constraints. The programmer states what must be true of a solution.

# Programming languages: imperative paradigm

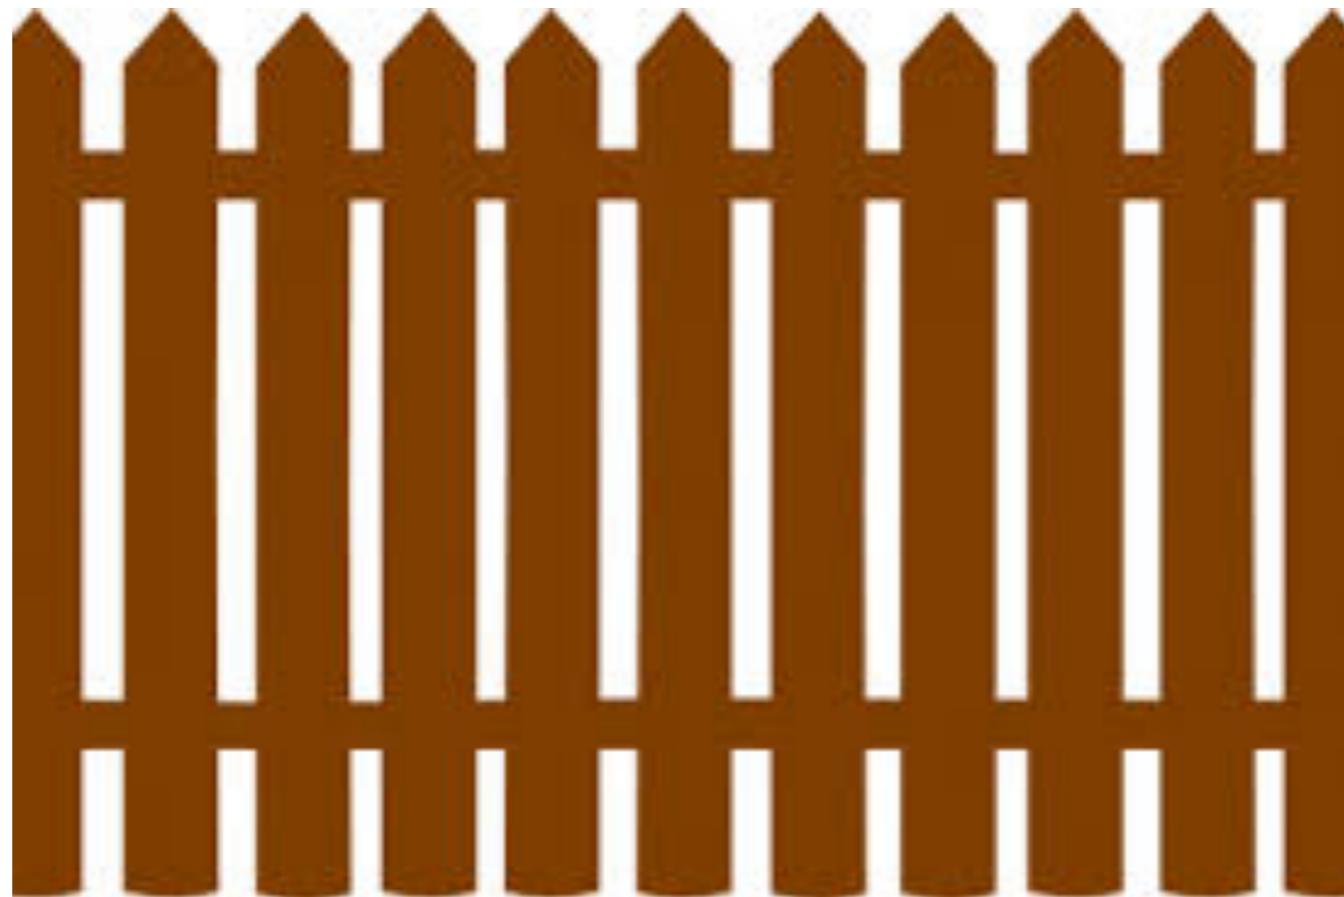

```
Place first board and rails  
While fence incomplete:  
    move half-a-foot to the left  
    position a new board  
    position a nail  
    hammer nail into top rail  
    ...
```

# Programming languages: functional paradigm

```
function build_fence(len):
    if len == 1:
        return rails_and_first_picket()
    else:
        return add_one_picket(build_fence(len-1))
```

# Programming languages: logical paradigm

```
def fence.  
fence is 5 ft tall.  
fence has two rails.  
fence has 50 pickets,  
    each picket is 4" wide  
every picket is 2" from at least one other.
```

C++ is a superset of C with object-oriented features and generics/templates.

**Focusing on classic/vanilla C++ written from scratch...**

**C/C++**

C/C++ is an example of the *imperative, structured, procedural, static, and object-oriented* language paradigms.

## Introduction to C++ ***syntax*** and ***semantics***

# C/C++

The ***syntax*** of a language is the rules one must follow for a program to be parsed correctly. E.g., braces must match {...}, identifiers begin with a character in [A-Za-z], semi-colons, etc.

The ***semantics*** of a language is the rules by which programs are run or evaluated to a result or behavior. E.g., operator precedence, order of operations, dynamic dispatch (which method is it), etc.

# C++ syntax: comments

```
/* Multi-line or “C style” comments begin with a slash-star  
*****  
...and end with star-slash */
```

```
// Single-line or “C++ style” comments start with two slashes  
// and end with a newline
```

```
/* Multi-line comments cannot be nested  
...like this: /* */ // <- this closes the whole comment  
 */ // <- this dangles
```

# C++ syntax: identifiers, strings, numbers

(The basics are very similar to Java, as Java was designed to have C-like syntax.)

**IDs match `[_a-zA-Z][_a-zA-Z0-9]*`,  
and are not reserved keywords**

x  
`_0123`  
`A_0`  
`a12`

**Numbers can take a number  
of forms in C/C++... e.g.**

`2.0, 2f`  
`0xffff00ff`  
`30500ULL`

**Characters are between single-quotes: e.g., 'a', '\n'**  
**Strings are between double-quotes: "Hello World\n"**  
**Strings in C/C++ are just arrays of chars: e.g., `char[16]`**

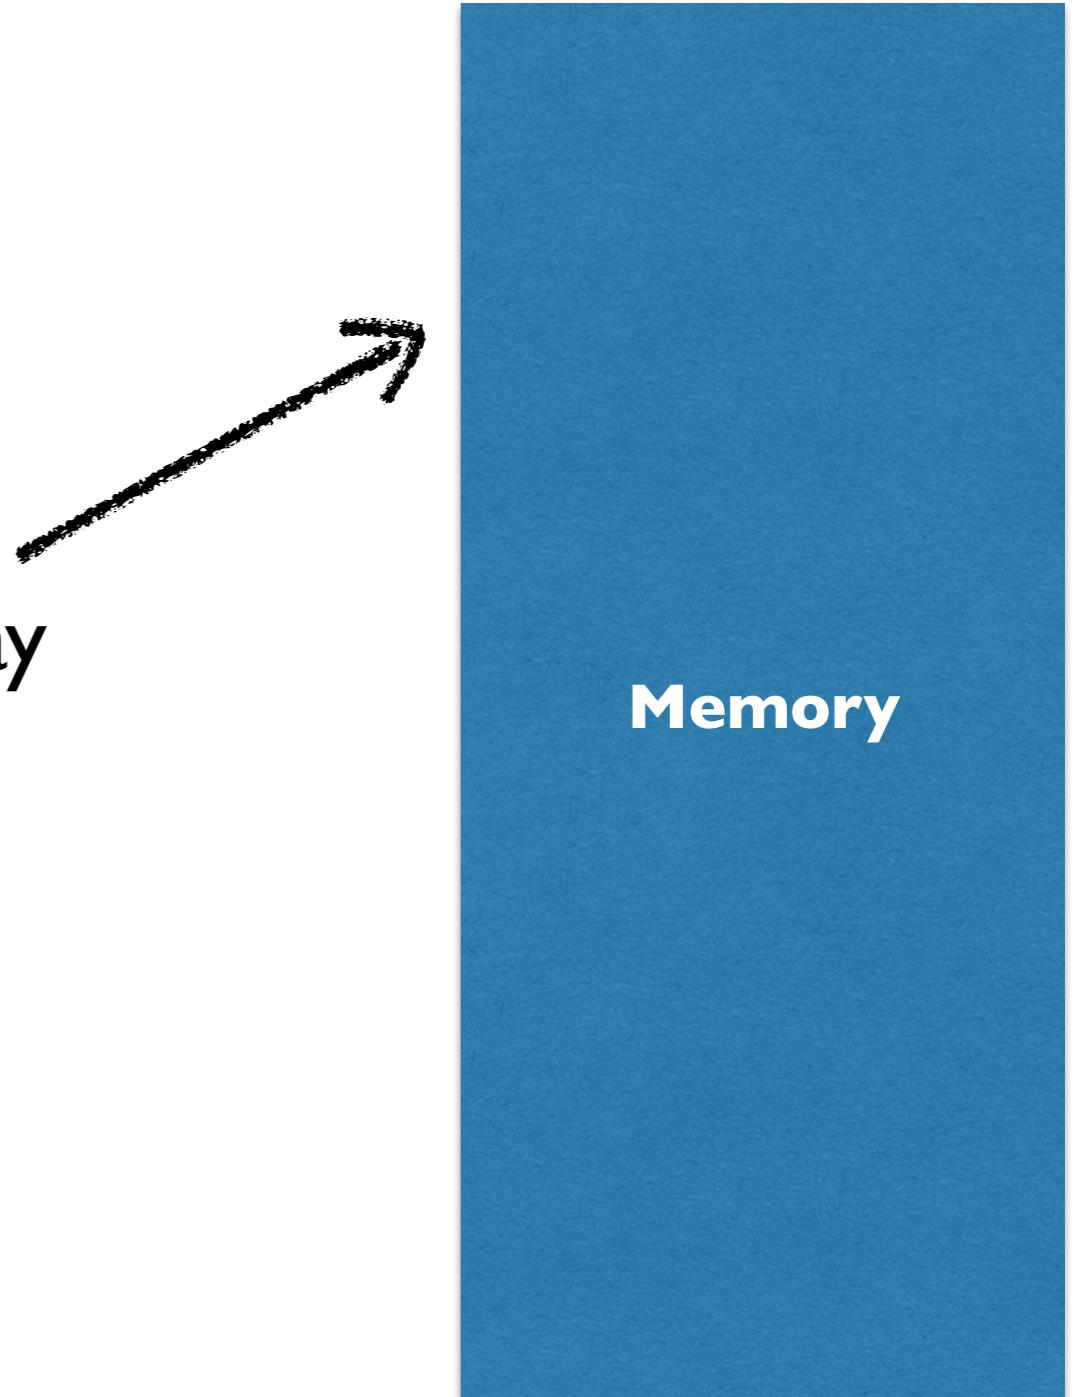

# C++ syntax: reserved keywords

# C++ semantics: memory model

Each variable in C++ exists somewhere in memory

C++ thinks of this as a giant array of bytes

# C++ semantics: memory model

char

Note: some lengths differ  
depending on architecture

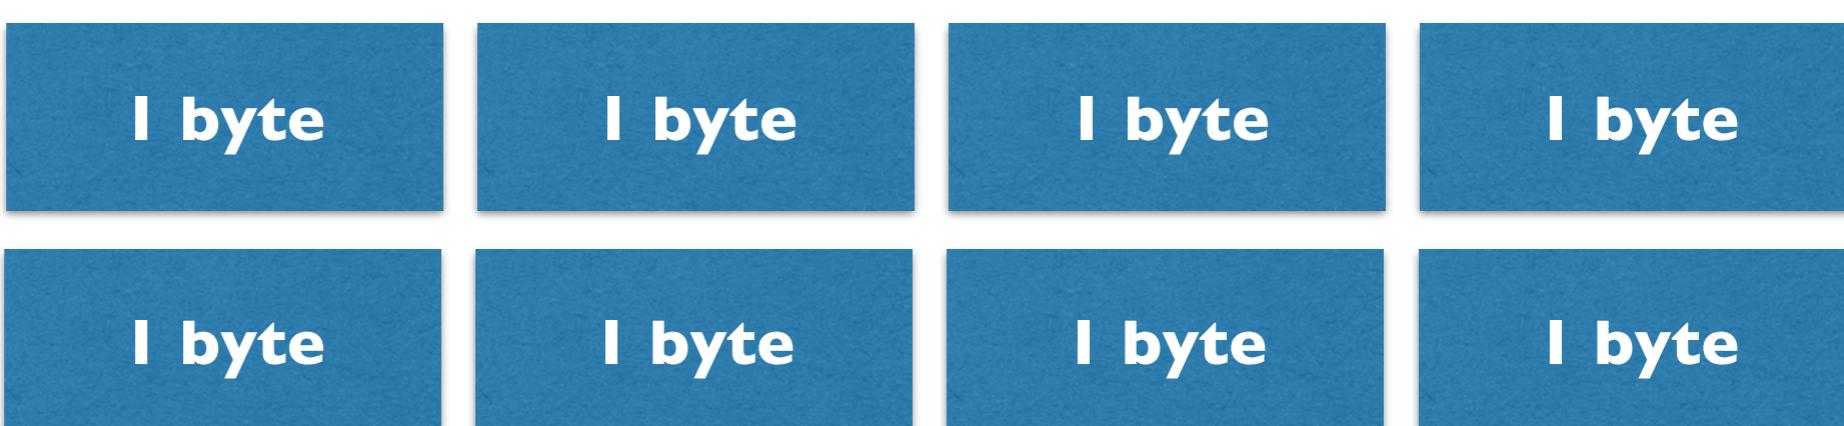

u16

int

long long

(for a 32-bit architecture...)

# C++ syntax: includes and macros

**By convention, .cpp files are used for source, .h for libraries/declarations.**

**#include “path/to/file.h”**

**#include will textually replace this line with the entire contents of a file.**

**#include <library>**

**#define defines a macro: in this case,  
textually replace occurrences of “MAX” with “255”.**

**#define MAX 255**

# C++ syntax: anatomy of a function

**The smallest valid C program.**

```
int main()
{
    return 0;
}
```

# C++ syntax: anatomy of a function

**The smallest valid C program.**

**main(...) is the entry-point of the program**

Annotations for the code:

- A large arrow points to the word **main**.
- An arrow points to the closing brace **}**.
- An arrow points to the **return** statement.
- A large arrow points to the closing brace **}**.
- A text box states: **Returns status code 0, success.**
- A text box states: **All statements end with a semi-colon, as in Java.**

```
int main()
{
    return 0;
}
```

**In C/C++ the preferred style is for curly braces  
to line up on the same row or column.**

**As in Java though, whitespace only separates tokens  
and is not otherwise meaningful.**

# C++ syntax: anatomy of a function

“Hello World”

```
#include <iostream>

int main()
{
    std::cout << "Hello World"
                << std::endl;
    return 0;
}
```

# Clang++: compiling and running

## “Hello World”

```
$ clang++ -o hello hello.cpp  
$ ls  
hello      hello.cpp  
$ ./hello  
Hello World  
$
```

**-g compiles for debugging,**  
**-std=c++14 compiles with c++14 features**  
**-O2 compiles with optimization level 2**

# C++ syntax: arrays, dereferencing a pointer

An array (len=5) can be allocated on the stack using syntax `T a[5];`  
or on the heap using syntax `T* a = new T[5];`

Using the prefix, unary operator `*` will explicitly dereference a pointer.  
if `a` is of type `int*`, then `*a` is of type `int`.

```
int main()
{
    int* iarr = new int[5];
    *iarr = 99;
    // is the same as
    iarr[0] = 99;
    // ...
}
```

# C++ syntax: structs

**A custom type containing two publicly visible fields: x, and y.**

```
struct Point
{
    int x;
    int y;
};

int main()
{
    Point p;
    p.x = 5; // field access
    //...
}
```

# C++ syntax: new and delete

**keyword “new” allocates an object on the heap, “delete” frees it**

```
struct Point
{
    int x;
    int y;
};

int main()
{
    Point* p = new Point();
    p->x = 5; // Same as (*p).x = 5
    delete p;
    //...
}
```

# C++ syntax: pass by reference

Using `T&` in place of `T*` means the pointer itself cannot be manipulated and dereference is implicit! These are called **references**.

```
bool x_gt_y(const P& p)
{
    return p.x > p.y;
}
```

# C++ semantics: reading command-line arguments

**Give main arguments argc and argv as below.**

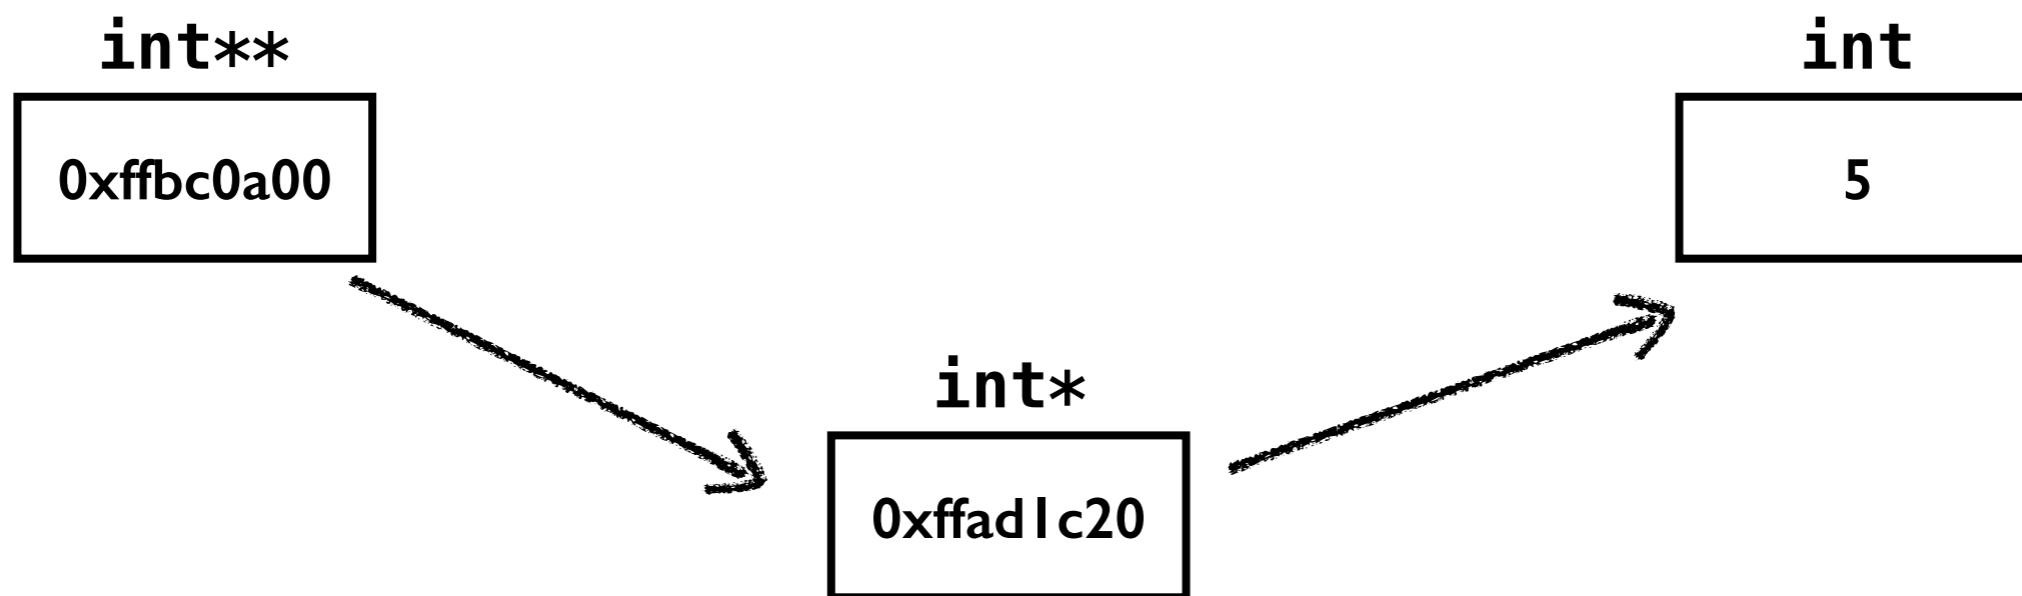

```
#include <iostream>

int main(int argc, const char** argv)
{
    if (argc <= 1) return 1; // failure
    std::cout << argv[1]
              << std::endl;
    return 0; // success
}
```

# C++ semantics: pointers

A type  $T^*$  means a pointer to something of type  $T$ .

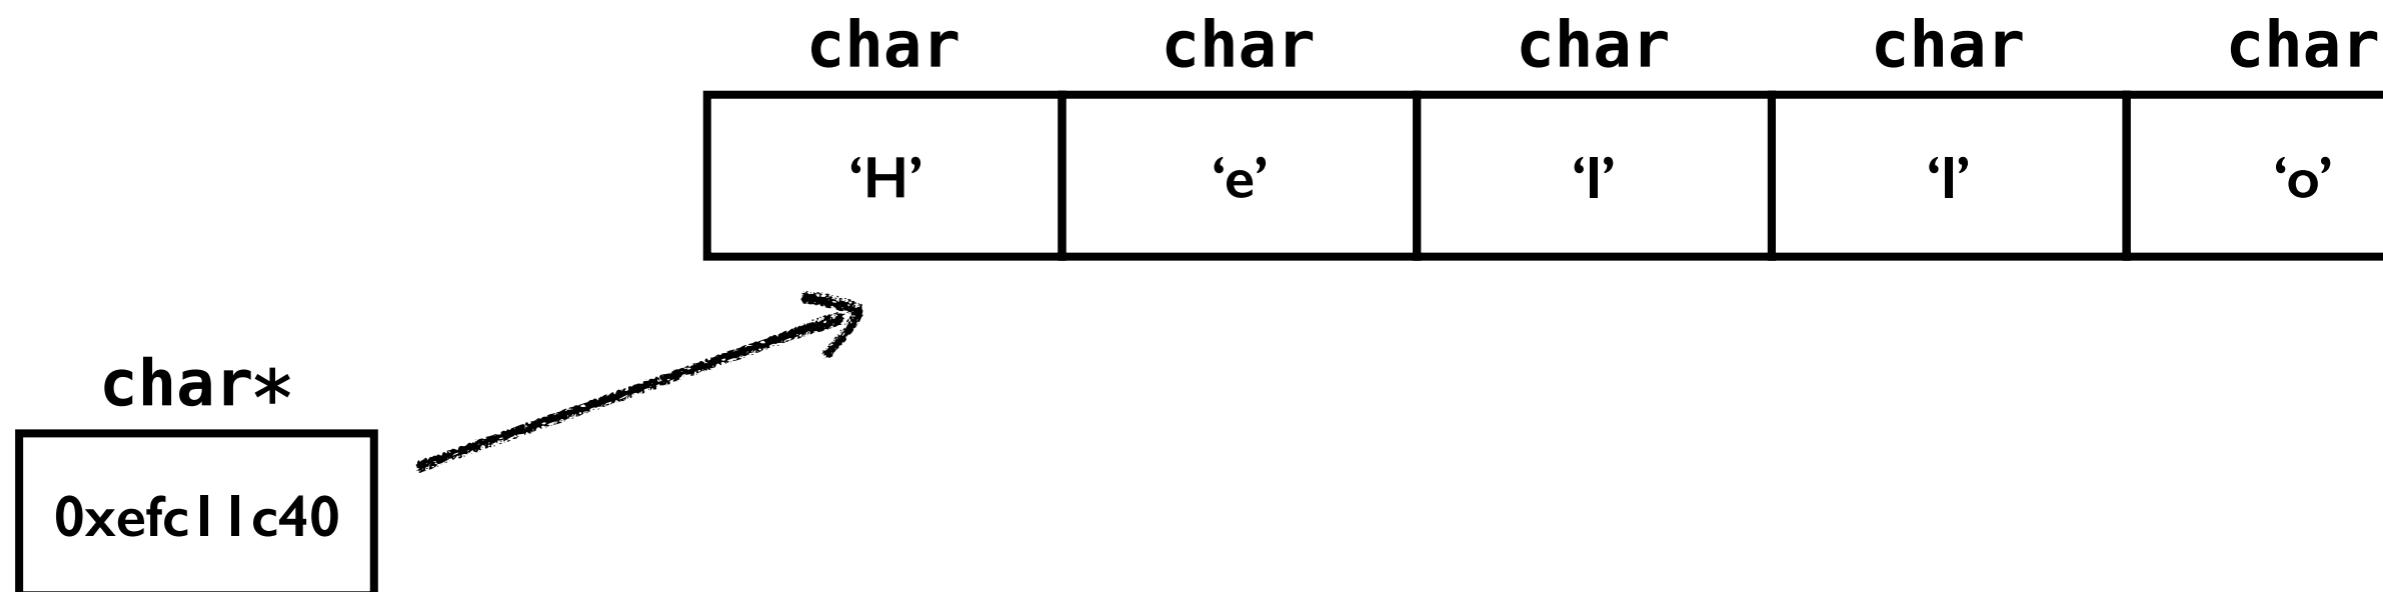

For example, an  $\text{int}^*$  is a word of memory containing the location, in memory, of an integer. An  $\text{int}^{**}$  is an address pointing to a location containing an address to an integer.

# C++ semantics: pointers

Pointers in C do not have lengths. You can read as many words or bytes at the location as you wish. Thus pointers are all really arrays of length 1 or greater.

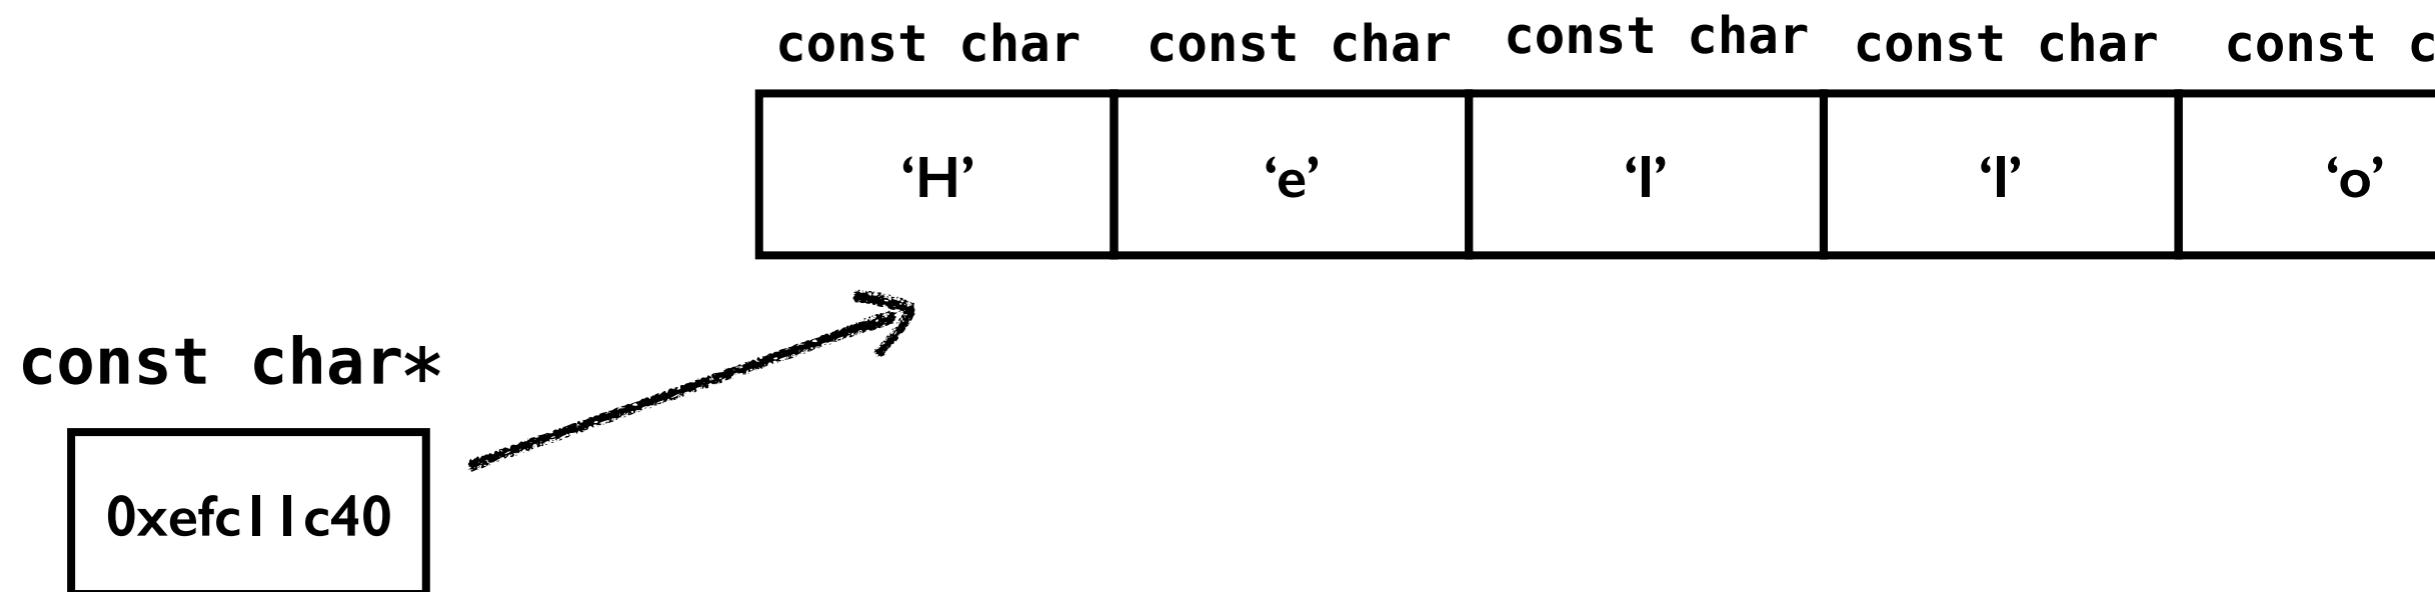

A string in C is just an array of chars, or a `char*`

# C++ semantics: const pointers

A type may be preceded by keyword `const`, this tells the compiler to check that the value cannot be modified!

A `const` string in C is a `const char*`

If the pointer itself is also `const`, then it is a `const char* const`

**Let's try out some examples**
